#### **Triple Science**

Revision information for Mock 2.

You will sit a Paper 2 in Biology, Chemistry and Physics, each paper is 1hr 45mins covering the following topics.

#### **Biology**

Homeostasis and response

Inheritance, variation and evolution

Ecology

#### Chemistry

The rate and extent of chemical change

Organic chemistry

Chemical analysis

Chemistry of the atmosphere

Using resources

#### **Physics**

Forces

Waves

Magnetism and electromagnetism

**Space Physics** 

Bold – Triple content

Forces and	1. Scalar quantities have a magnitude (size) only and can be represented by a line.
their	2. Examples of Scalar quantities include speed, distance, time, mass, energy and power.
interactions	3. Vector quantities have a magnitude and direction and are represented by an arrow,
	showing the direction of the vector.
	4. Examples of Vector quantities include velocity, acceleration, force, momentum,
	weight, gravitational field strength and displacement.
	5. Displacement is defined as distance without a change of direction.
Forces	6. A force can be a push a pull or a twist and changes the shape or motion of an object.
between	7. Forces work in pairs known as action reaction pairs.
objects	8. Contact forces are only able to act when the objects are physically touching.
	9. Examples of contact forces include, thrust, upthrust, lift, reaction, tension, friction and drag forces (air and water resistance)
	10. Non-contact forces are able to act at a distance.
	11. Examples of non-contact forces include weight, magnetic and electrostatic force.
	12. Scale diagrams can be used to show the size of forces in free body force diagrams,
	the size of the arrow represents the size of the force.
Weight and	13. Weight is the force action on an object due to gravity.
Gravity	14. The magnitude of gravity on the earth is given as 9.8N/kg
Gravity	15. Everything near the earth experiences gravity and weight due to the proximity to
	earth
	16. The weight of an object is given as weight (N) = mass (kg) x gravitational field
	strength(N/kg)
	17. The weight of an object is said to act from the objects centre of mass
	18. Weight is measure in Newton's using a calibrated spring balance called a
	Newtonmeter
Resultant	19. A number of forces acting on an object may be replaced by a single force that has the
force	same effect as all the original forces. This is known as resultant force.
300000000000000000000000000000000000000	20. Resultant force is calculated by adding forces in the same direction and subtracting
	forces in the opposite direction.
	21. A single force can be calculated using Pythagoras theorem when the forces are at
	right angles. Using parallelograms of forces when they are at any other angle.
	22. Resultant force diagrams must be drawn to scale and using arrows.
	23. A single force can also be resolved to give two forces acting at right angles to each
	other. Often known as the horizontal and vertical component.
Friction and	24. Friction and drag forces oppose motion.
Drag	25. Friction forces are between solid surfaces and increase as the mass of the object
	increases.
	26. Drag forces, (air resistance and water resistance) are caused by the collision of the
	particles in the medium the object is moving through with the object.
Work done	27. When a force causes and object to move through a distance work is done on the
and energy	object.
,	28. One joule of work is done when one newton of force causes and object to move 1
	metre.
	29. Work done (J) = force (N) x distance (moved along the line of action of the force) (m)

	T	
Forces	Moments	<ul><li>30. A moment is a turning effect caused by a force or system of forces.</li><li>31. The size of the moment is defined by the equation moment of force (Nm) = force (N) x distance (perpendicular distance from the pivot along the line of action of the force) (m)</li></ul>
		32. Where an object is balanced the clockwise rotation is equal to the anticlockwise rotation
		33. Force or distance can be calculated in a balanced system using the moment
		equations and rearrangements of this equation.
		34. One Nm is equal to one Joule
		35. Levers and gear systems can be used to reduce effort and increase force and can be described as force multipliers.
		36. There are two types of gears, low gears (step up) which are designed to minimise
		the force and give a high turning effect, and high gears (step down) which require more force but give out greater speed and low turning effect.
	Forces and	37. An object can be changed shape if more than force is applied to it.
	elasticity	38. A stretching force puts an object under tension and a squashing force puts an object under tension.
		39. An object is elastic if it returns to its original shape when the forces deforming are removed.
		40. If an object reaches its elastic limit then it will no longer return to its original shape, this is known as inelastic deformation
		41. The extension of an elastic object is directly proportional to the force applied, provided the limit of proportionality is not exceeded.
		42. This is given by the equation, force $(N) = \text{spring constant } (N/m) \times \text{extension } (m)$
		43. A force that stretches or compresses a spring does work and elastic potential energy
		is stored. Provided the elastic limit has not been met.
	Pressure	44. A fluid can be either a liquid or a gas
	and	45. The pressure in a fluid causes a force that is normal (at right angles) to any surface.  46. Pressure (Pa) = force normal to a surface (N)/ area of the surface (m²)
	pressure differences	47. Pressure in fluids increases with depth as the weight of the particles above push
	in fluids	down on the particles below.
	minaias	48. This is given by the equation pressure (Pa) = height of the column (m) x density of the liquid (kg/m³) x gravitational field strength (N/kg)
		49. An object that is submerged (partially or totally) experiences a greater pressure on
		the bottom surface than the top surface caused by difference in height and this creates a resultant force upwards known as upthrust.
		50. An object that displaces a greater mass of water than its own mass will float. This
		object will also have a density less than the fluid it is in.  51. The atmosphere of the earth is a thin (relative to the thickness of the earth) fluid
		layer round the earth.
		52. The atmosphere gets less dense with increasing altitude. 53. Air molecules colliding with a surface creates atmospheric pressure.
		53. Air molecules colliding with a surface creates atmospheric pressure.

	Forces and	54. Speed is a scalar quantity.
	Motion	55. Velocity is a vector quantity and represents speed with a direction.
		56. The speed of an object can be calculated using the equation,
		speed (m/s) = distance (m) ÷ time (s)
T	Distance-	57. The gradient of a line on a distance-time graph represents the speed
orc	Time	58. The object is stationary if the line is horizontal and the gradient of the line is 0.
Forces	Graphs	59. The object is moving at a constant speed if the gradient is a straight line sloping upwards.
		60. The steeper the gradient on a distance-time graph, the faster the speed of the object.
		61. For an object moving at changing speed, the speed, at any instant in time, can be
		calculated by drawing a tangent to the line and finding the gradient of the tangent.
	Acceleration	62. Two moving objects can have the same speed but different velocities if they are moving in different directions.
		63. An object moving in a circle may have a constant speed but a changing velocity as it's
		direction is continuously changing as it goes round.
		64. Acceleration is the change in velocity per second.
		65. Acceleration can be calculated using the equation,
		Acceleration $(m/s^2)$ = change in velocity $(m/s) \div$ time taken for the change $(s)$
		66. The change in velocity can be calculated using the equation,
		Change in velocity (m/s) = final velocity (m/s) — initial velocity (m/s)
		67. Deceleration is the change in velocity per second when an object slows down and can
		be calculated using the same equation as acceleration.
		68. The following calculation can be useful when time taken is not given and acceleration
		is constant, $(\text{final velocity})^2 - (\text{initial velocity})^2 = 2 \times \text{acceleration } \times \text{distance}$ .
	Velocity-	69. The gradient of a line on a velocity-time graph represents the acceleration.
	Time	70. A horizontal line with a gradient of 0 means the acceleration is 0, this means the
	Graphs	object is moving at a constant velocity.
		71. A straight line sloping upwards represents acceleration and therefore an increasing velocity.
		72. A straight line sloping downwards represents deceleration and therefore a decreasing velocity.
		73. A steeper the gradient on a velocity-time graph, tells you an object accelerates faster.
		74. The area under the line on a velocity-time graph represents the distance travelled.
100-10		You can use the equation, area = base x height (for a rectangle) or area = $\frac{1}{2}$ x base x
. Those		height (for a triangle)
	Force and	75. If a resultant force of an object is zero, a stationary object will remain stationary and
	Acceleration	a moving object will continue to move at the same speed and direction (velocity).
		76. Resultant force (N) = mass (kg) x acceleration $(m/s^2)$
		77. The greater the resultant force on an object, the greater the acceleration.
		78. The greater the mass of an object, the smaller its acceleration (for a given force).
		79. Acceleration is always in the same direction as the resultant force.
		80. The inertia of an object is its tendency to stay at rest of in uniform motion.
		81. Inertial mass is a measure of how difficult it is to change the velocity of an object.

Bold – Triple content

-	Terminal	82. Weight is the force due to gravity, measured in Newtons. Mass is the amount of
o o	Velocity	matter in an object, measured in kilograms.
Forces	velocity	83. An object on earth that is free falling under gravity has an acceleration of about
S		9.8m/s <sup>2</sup> .
		84. The terminal velocity of an object is the velocity it eventually reaches when it is
		falling.
		85. At terminal velocity, the resultant force acting on the object will be zero.
	Newton's	86. Newton's first law of motion states that an object remains in the same state of
	Laws	motion unless a resultant force acts on it.
1000	Laws	87. If the resultant force is zero, a stationary object remains stationary and an object in
		motion continues to move at the same velocity.
		88. Newton's second law of motion can be describe by the equation
		Resultant force (N) = mass (kg) x acceleration (m/s <sup>2</sup> )
		89. Newton's third law of motion states that when two objects interact they exert equal
		and opposite forces on each other.
	Forces and	90. Friction and air resistance oppose the driving force of a vehicle.
	Braking	91. Stopping distance is the shortest distance a vehicle can stop in.
	Diaking	92. Thinking distance is the distance travelled by the vehicle in the time it takes the
		driver to react.
		93. Braking distance is the distance travelled during the time the braking force is applied.
		94. Stopping distance (m) = thinking distance (m) + braking distance (m).
		95. Force (N) = mass (kg) x acceleration (m/s <sup>2</sup> ) gives the braking force of a vehicle.
		96. Reaction time can be affected by factors such as tiredness, drugs and alcohol.
		97. Braking distance can be affected by factors such as the condition of the vehicle and
		adverse road and weather conditions.
		98. The greater the speed a vehicle is travelling, the greater the braking force needed to
		stop the vehicle.
		99. The greater the mass of a vehicle, the greater the braking force needed for a given
		deceleration.
	Momentum	100. Momentum (kg m/s) = mass (kg) x velocity (m/s)
		101. A closed system is a system in which the momentum before an event is equal to the
		total momentum after the event. This is called conservation of momentum.
		102. The conservation of momentum only exists if there are no external forces acting on
		the objects.
		103. Momentum is a vector quantity, so it is important to consider both magnitude and
		direction. For example, if travelling east is given a positive value, travelling west is
		given a negative value.
		104. Two objects pushing apart in opposite directions will have equal and opposite
		momentum causing the total momentum of the system to be zero. The two objects
		may be of different masses and therefore travelling at different speeds.
		105. For the two objects (A and B) we can use this equation;
		(mass A x velocity A) + (mass B x velocity B) = 0

	Change in	106. When a force acts on an object that is able to move, a change in momentum occurs.
	momentum	107. To calculate the force involved when a change in momentum occurs we can use
		these two equations;
		Force = mass x velocity and acceleration = change in velocity ÷ time
		Combined to form the following equation;
		Force (N) = $(mass (kg) \times change in velocity (m/s)) \div time$
		108. The force is therefore equal to the rate of change of momentum.
		109. For a collision, the shorter the impact time, the greater the impact force.
		110. Car safety features such as seatbelts, airbags and crumple zones all work to change
		the shape of the car, which increases the time taken for the collision and therefore
		reduce the impact force.
5	General	111. Waves transfer energy without a transfer of matter, there are two type mechanical
Waves	wave	and electromagnetic
/es	properties	112. Mechanical waves are vibrations that travel through a medium (a substance) and
		include water waves, sound waves, waves on a spring or rope and seismic waves
		113. Electromagnetic waves are able to travel through a vacuum at the speed of light, 3 x
		10 <sup>8</sup> m/s and include light, radiowaves and microwaves.
		114. In transverse waves the oscillations are perpendicular to the direction of energy
		transfer. All electromagnetic waves are transverse
		115. In longitudinal waves the oscillations are parallel to the direction of energy transfer.
		116. Mechanical waves can be either transverse or longitudinal
		117. In longitudinal waves there are areas of compression (squashing) and rarefaction
		(spreading out)
		118. The wavelength ( $\lambda$ ) of a wave is the distance from one point on one wave to the same
		point on the next wave and is measured in meters.
		119. The amplitude of a wave is the maximum displacement of a point on the wave from
		its undisturbed position. Eg from the middle to the peak.
		120. The bigger the amplitude of the waves the more energy the waves carry.
		121. Frequency is the number of waves that pass a fixed point every second and is
		measured in Hertz
		122. The (time) period of a wave is the time taken for each wave to pass a fixed point and
		is measured in seconds
		123. Frequency and time period are related with the following equation. (This equation is
		given to you.)
		$time\ period\ (seconds) = \frac{1}{frequency\ (Hertz)}$
		124. The speed of the wave is the distance travelled by each wave every second.
		125. The wave speed can be calculated using the following equation.
		wave speed $v = frequency \int x wavelength \lambda$
		m/s = Hertz Hz  x  metres

Reflection	126. When waves such as water waves sound waves and light waves hit a solid surface
and	they reflect at the same angle as the incident angle. This is called the law of
refraction	reflection.
	127. At the boundary between two materials waves can either be transmitted (pass through) or absorbed.
	128. Refraction occurs in water waves at different depths. Water waves travel slower in
	shallower water than they do in deeper water.
Sound	129. Sound waves cannot travel in a vacuum as they require particles
waves	130. Sound waves can travel in all three states of matter and travel the fastest in solids the particles are closest together
	131. The speed of a wave in solids can be measured using a frequency generator attach
	to a vibration generator and a length of string under tension to set up a standing wave.
	132. The speed of a wave in a liquid can be measured using a frequency generator
	attached to a paddle/dibber in a ripple tank. A slow motion camera can be used to measure the wavelength and frequency to determine the speed.
	133. The speed of a sound wave in air can be measured by making a sound and waiting
	hear the echo off of a smooth solid object such a wall.
	134. On an oscilloscope the louder the sound the larger the amplitude of the wave, the
	higher the pitch of the sound the shorter the wavelength is.
	135. The human hearing range is between 20 – 20 000 Hz
	136. Sound waves are detected by the ear. Vibrations in the air are caught by the pinn
	and cause the eardrum to vibrate. These vibrations are amplified by the ossicles
	before passing into the cochlea where they are converted into electrical signals to
	be sent to the brain.
	137. Sounds above 20 000 Hz are called ultrasound. They can be used in pregnancy
	scanning, breaking down kidney stones and echo sounding.
	138. Echo sounding and pregnancy scanning both work by sending a high frequency sound wave which reflects on a boundary before being detected. The distance to the object is then therefore equal to half the speed x time. S= 1/2vt
	139. In pregnancy scanning the ultrasound wave is partially reflected a boundary
	between tissues and detected by the transducer. This allows a 2D or 3D image to
	viewed on a screen.
	140. Ultrasound waves are not ionising and therefore safer than an X-ray.
Seismic	141. Seismic waves are produced in an earthquake and can travel through the earth
waves	spreading out from the epicentre.
	142. Primary seismic waves (P waves) are longitudinal waves. Secondary seismic wave
	(S waves) are transverse waves.
	143. P waves can travel through liquids and solids but refract at the boundaries. S wa
	can not travel through the liquid core.
	144. S waves can only be detected up to 105° to either side of the earthquake. P wave
	can be detected up to 105° and after 142°. Between these two points is called the
	shadow zone where there are no P or S waves.
	145. It is the information on earthquake waves that has allowed us to determine the
	structure of the earth.

# 

5	Electro-	146. The order of the electromagnetic spectrum from longest wavelength to shortest
Waves	magnetic	wavelength is Radio waves, Microwaves, Infra-red, Visible light, Ultraviolet, X-rays,
Ves	waves	Gamma rays.
0,		147. Radio waves can be up to 1x 10 <sup>4</sup> m (10 km) they are used for sending sound and
		images in TVs and radios and for Bluetooth signals. They have the lowest frequency
		between 300 000 to 3000 million Hz
		148. Microwaves have shorter wavelengths than radio waves and higher frequencies.
		They are used for satellite TV, mobile phone signals and heating food in microwave
		ovens.
		149. Infra-red waves are shorter in wavelength and higher in frequency than microwaves.  Anything that is hot emits infrared radiation and they can be used for remote
		controls, body scanning, thermal imaging and optical fibres.
		150. Visible light can be divided into the seven colours of light. Red, Orange, Yellow, Green, Blue, Indigo, Violet. They are used in cameras and to be able to see.
		151. UV radiation is shorter in wavelength and higher frequency than visible light. It can
		be used for tanning, security checks on money, finding body fluids at a crime scene.
		152. X rays are shorter wavelength and higher frequency than UV rays It is used for
		detecting broken bones and airport security.
		153. Gamma rays are the shortest wavelength and the highest frequency. They carry the
		most energy and can be used for sterilising medical equipment, treating cancer and
		detecting flaws in metals or concrete.
		154. Electromagnetic waves are given off when electrons are excited to higher energy
		levels and drop back down.
	Communica	155. Radio waves, microwaves, infra-red and visible light can all be used to send
	tions	messages
		156. Infra-red and visible light can be used to send messages down optical fibres using a process called total internal reflection.
		157. Radio waves can be used to send information signals around the world by bouncing
		them off the ionosphere. Radio waves can not pass through the atmosphere
		158. Microwaves can be used to send information around the world by bouncing them of satellites.
	4	159. Microwaves spread out less than radio waves and therefore give a higher quality
		signal. Hence the switch to digital signals in recent years.
36.43.55		160. Radio waves have different ranges. MW and LW over 100m are used for international
		broadcasts. FM are used in local broadcasts as they can travel only short distances.
		161. Sound is converted into an AC current using a microphone, in a modulator this is
		causes an electron to become excited and emit radio waves. These are then received
		by a different radio mast and converted back into AC current which can be converted
		into sound by a speaker.

Bold – Triple content

caused by heating molecules.  163. High frequency UV radiation, X-rays and Gamma rays are all ionising, this means they can cause mutations in DNA leading to cancer.  164. UV radiation is lowly penetrating and can be stopped using sunscreen and sun glasses. It can cause skin cancer and cataracts.  165. X-rays and Gamma rays are more penetrating and a film badge is used to monitor exposure.  166. X rays and gamma rays are used in hospitals because the benefits outweigh the risks.  167. X rays can pass through soft tissues but are absorbed by denser tissues such as bones and teeth. These areas show up clear on a film.  Infra-red radiation  168. Infra-red radiation is absorbed and emitted by all objects. The hotter they are the more infra-red radiation is given off.  169. An object at a constant temperature emits as much infrared radiation as it absorbs. 170. The perfect absorber of radiation is called a black body. It is also by the same logic a perfect emitter of radiation.  171. Black matt surfaces are the best absorbers/emitters of infrared.  172. This can be proved using a Leslie cube, or black and white cans with boiling water.  173. Light travels in straight lines.  174. When light hits a smooth shiny surface, it is reflected according the laws of reflection and give a clear image. This is known as specular reflection.  175. When it hits a rough object the light is reflected according to the law of reflection but is scattered in all directions called diffuse scattering.  176. The law of reflections states that angle of incidence is equal to the angle of refraction.  177. The angle of incidence is measured between the normal line and the incident ray.  178. The normal line is perpendicular to the surface.  179. Light travels slower in more dense materials and refracts.  180. When light waves cross a boundary between mediums they are refracted, this is because waves travel slower in more dense mediums and consequently bend towards the normal.  181. When a light ray refracts as it travels from air to glass, th	Wa	Harm	162. Microwaves, radiowaves and infra-red radiation all pose a risk to health through heating. There is a strong correlation between mobile phones and cancer possible
163. High frequency UV radiation, X-rays and Gamma rays are all ionising, this means they can cause mutations in DNA leading to cancer.  164. UV radiation is lowly penetrating and can be stopped using sunscreen and sun glasses. It can cause skin cancer and cataracts.  165. White shiny surfaces are the worst absorbers/emitters of infrared.  172. This can be proved using a Leslie cube, or black and white cans with boiling water.  173. Light travels in straight lines.  174. When light hits a smooth shiny surface, it is reflected according the laws of reflection and give a clear image. This is known as specular reflection.  175. When it hits a rough object the light is reflected according to the law of reflection but is scattered in all directions called diffuse scattering.  176. The law of reflections states that angle of incidence is equal to the angle of refraction.  177. The angle of incidence is measured between the normal line and the incident ray.  178. The normal line is perpendicular to the surface.  179. Light travels slower in more dense materials and refracts.  180. When light waves cross a boundary between mediums they are refracted, this is because waves travel slower in more dense mediums and consequently bend towards the normal.  181. When a light ray refracts as it travels from air to glass, the angle of incidence is less than the angle of incidence. When it exits the glass the opposite is true.  182. The refraction of light in a prism is called dispersion and it splits light into the seven colours.  183. Violet light is the shortest wavelength and is refracted the most in a prism. Red			
Infra-red radiation  168. Infra-red radiation is absorbed and emitted by all objects. The hotter they are the more infra-red radiation is given off.  169. An object at a constant temperature emits as much infrared radiation as it absorbs. 170. The perfect absorber of radiation is called a black body. It is also by the same logic a perfect emitter of radiation.  171. Black matt surfaces are the best absorbers/emitters of infrared. White shiny surfaces are the worst absorbers/emitters of infrared.  172. This can be proved using a Leslie cube, or black and white cans with boiling water.  173. Light travels in straight lines.  174. When light hits a smooth shiny surface, it is reflected according the laws of reflection and give a clear image. This is known as specular reflection.  175. When it hits a rough object the light is reflected according to the law of reflection but is scattered in all directions called diffuse scattering.  176. The law of reflections states that angle of incidence is equal to the angle of refraction.  177. The angle of incidence is measured between the normal line and the incident ray.  178. The normal line is perpendicular to the surface.  179. Light travels slower in more dense materials and refracts.  180. When light waves cross a boundary between mediums they are refracted, this is because waves travel slower in more dense mediums and consequently bend towards the normal.  181. When a light ray refracts as it travels from air to glass, the angle of incidence is less than the angle of incidence. When it exits the glass the opposite is true.  182. Bold – Triple content

	Colours of	184. A coloured object appears to be the colour it is because it reflects the colour of light
	light	that it is. Eg a red object reflects red light
		185. A coloured filter is transparent or translucent. It allows the colour of light the same
		as the filter to pass through it. Eg a red filter transmits red light.
		186. The primary colours of light are Red, Green and Blue.
		187. The secondary colours of light are made by mixing the primary colours. Red and
		green make yellow, red and blue make magenta, green and blue make cyan.
		188. Secondary colour filters let through the colour of the filter plus the two primary
		colours they are made up from. Eg a Yellow filter will let yellow, red and green light
		through.
		189. If a coloured object is seen under a coloured light then it will appear black unless
		the colour of the object is present in the colour of the light. in that case it will
		appear the colour that can be reflected. Eg a magenta object under a blue or cyan
	Lana	light will appear blue, but would appear black under a green light.
	Lenses	190. Lenses change the direction of light passing through it by refraction.
		191. A convex lens (converging lens) makes parallel rays converge to a focus. This is
		called the focal point. An example is a magnifying glass.  192. A concave lese (diverging lens) makes parallel rays diverge (spread out). The point
		where the light appears to come from is the principle focus. An example is a glasses
1.5		used to fix short sightedness.
The second		193. The distance from the middle of the lens to the focal point or principle focus is
		called the focal length.
100		194. Convex lens will give a real image (one that can be projected onto a screen) if the
		object is placed further than the focal length from the lens.
1000		195. A convex lens will give a virtual image if the object is placed between focal point
		and the lens.
		196. A concave lens can only ever give a virtual image.
		197. The magnification of a lens is $magnification = \frac{image\ height}{object\ height}$
		198. Lens diagrams can be constructed to calculate the size and position of the image by drawing the 3 rays of light.
7	Magnets	199. The three magnetic elements iron, cobalt and nickel. Steel is magnetic because it
a		contains iron. They are magnetic because of the dipoles.
Magnetism		200. The poles of a magnet are north and south. The magnetic field flows from north to
eti		south.
ms		201. Like poles repel, opposite poles attract.
		202. The magnetic field can be determined by using a compass or iron filings.
		203. The stronger the magnetic field is, the closer the lines of the magnetic field are
		together. This is called magnetic flux density.
		204. There are three types of magnet: permanent magnets, induced magnets and
		electromagents.
		205. Steel is used to make permanent magnets because it does not easily lose its magnetic
		abilities. Iron is used to make electromagnets because it does not retain its magnetic
		ability for long.
		206. The earth also has a magnetic field similar to that of a bar magnet.

Bold – Triple content

I	
Electromagn ets	207. Any wire carrying a current generates a magnetic field. This can be predicted using the right had grip rule, where your thumb gives the direction of flow and your curled fingers give the direction of the field
	208. Wrapping the wire into a coil increases the strength of the magnetic field. This is called a solenoid.
	<ul> <li>209. The electromagnetic field is strongest inside a solenoid and is similar to a bar magnet.</li> <li>210. The north pole of a solenoid is where the current is flowing in an anticlockwise direction. The south pole is where the current is flowing in a clockwise direction</li> <li>211. An electromagnet is made when that solenoid is wrapped around a soft iron core.</li> <li>212. Increasing the current makes the magnetic field stronger. Reversing the current reverses the direction of the magnetic field.</li> </ul>
	213. Electromagnets are used in many devices such as scrapyard cranes, circuit breaker, electric bell and relay switch.
	214. The electromagnet works in relays, circuit breakers and relay switches using an iron armature
The motor effect	215. When a current carrying wire is put in a magnetic field a force is experienced. This causes one to move. This is called the motor effect.
	216. This movement can be predicted using Flemings left hand rule. The thu <b>M</b> b represents <b>M</b> ovement, the <b>F</b> irst finger represents <b>F</b> ield, the se <b>C</b> ond finger represents <b>C</b> urrent.
	217. The size of the force can be increased by increasing the current or using a stronger magnet.
	218. The force is greatest when the wire is perpendicular to the magnetic field. There is no force when they two are parallel.
	219. The equation that links the force, magnetic field strength and current is force $F = magnetic \ flux \ density \ B \ x \ Current \ I \ x \ length \ l$
	Newtons N = tesla T  x  amperes A  x  metres  m
	220. An electric motor uses the motor effect by using a coil of wire. A split ring
	commutator keeps the motor spinning in the same direction. Because the current
	flows around the circuit. One side moves up and the other moves down in the magnetic field.
	The motor

7	The	221. When a wire is moved in a magnetic field a potential difference is induced (created)
/a	generator	as it crosses the field lines. If this wire is connected to a circuit then a current will
9	effect	flow. This is called the generator effect.
Magnetism		222. The faster the wire cuts through the magnetic field the bigger the induced potential
ms		difference.
		223. The direction of the an induced current always opposes the original change that
		caused it.
		224. Current is only produced when the magnet or wire is moving. Reversing the
		direction of movement reverses the direction of current flow.
		225. AC current can be generated using the generator effect by using a coil of wire that
		spins in a uniform magnetic field.
		226. This produces the typical AC trace because the most current is produced when the
		coil is perpendicular to the magnetic field, none is produced when it is parallel and
		as the coil changes rotates the current changes direction.
		227. The faster the coil rotates the bigger the frequency of the AC and the bigger the
		peak value.
		228. A DC generator works in a similar way but has a split ring commutator which keeps
		the current flowing in the same direction.
		229. Microphones use the generator effect to convert vibration into AC current.
		230. Speakers use the motor effect to convert AC into vibrations into sound waves.
	Transformer	231. Transformers can be used to change the size of alternating potential difference
	s.	from mains 230V to the required potential difference.
		232. Step up transformers have more coils on the secondary coil and increase the size of
		the potential difference.
		233. Step down transformers have less coils on the secondary coil and decreases the size
		of the potential difference.
		234. The first coil on a transformer works as an electromagnet. An AC current wrapped
		around the soft iron core causes a magnetic field that changes direction 50 times a
		second.
		235. The second coil works as the generator effect. The moving magnetic field induces a
		current in the second coil.
		236. Transformers only work with AC as DC does not cause a moving magnetic field. We
		use AC in the national grid because we can use transformers to increase the
		potential difference and reduce wasted energy
		237. The transformer equations is
		potential difference number of turns
		$\frac{accross\ primary\ coil\ ^{V_p}}{potential\ difference} = \frac{anumber\ of\ turns}{number\ of\ turns} \\ accross\ secondary\ coil\ ^{V_s} = \frac{on\ primary\ coil\ ^{n_p}}{number\ of\ turns} \\ on\ secondary\ coil\ ^{n_s}$
		potential difference $_{V}$ - number of turns $_{n}$
		accross secondary coil on secondary coil on secondary coil
		238. Transformers are almost 100% efficient. Which gives the equation:
		primary potential differnce $V_p x$ primary current $I_p$
		= secondary potential difference $V_s x$ seconday current $I_s$

Bold – Triple content

Sp	Life cycle of	239. A solar system comprises the planets, dwarf planets, moons and asteroids that
Space	stars	<ul> <li>orbit a star called a sun.</li> <li>240. A star is formed in stellar nebular, the remaining dust and gas left over from this stars formation will become the planets and other structures in the solar system.</li> <li>241. In a stellar nebula the dust and gas are pulled together by their own gravitational field attraction forming a protostar</li> <li>242. When it is dense enough fusion starts and the star is in the main sequence. Energy is released that balances the force of gravity pulling it in. converting hydrogen to helium.</li> <li>243. When the hydrogen runs out the star collapses until the pressure and temperature increases and fusion of helium can begin to form heavier elements up to iron, this is red giant phase.</li> <li>244. Depending on the size of the red giant it will form a white dwarf or a supernova.</li> <li>245. Smaller stars eventually run out fuel and collapse forming a white dwarf which cools to form a black dwarf.</li> </ul>
		246. Larger stars turn into red supergiants before exploding into a supernova. The very largest stars become a black hole. Elements heavier than iron are only made in these.
	Planets, satellites and orbits	<ul> <li>247. Planets orbit the sun in a circuit called an ellipse. Moons and satellites orbit planets in a circular orbit.</li> <li>248. In a circular orbit the speed is constant but the velocity is constantly changing because the direction is always changing</li> <li>249. Gravity pulls the object to the centre of the circuit, the velocity of the object is perpendicular to gravity. The planet experiences acceleration towards the centre of</li> </ul>
		the circle  250. To stay in orbit the satellite must move at the right speed around the larger body.  251. If a satellite is launched to close or too slow it will fall to earth. Too high or too fast and it will leave orbit.
	Big Bang	<ul> <li>252. The current theory of the start of the universe is the big bang theory. We know the universe is getting bigger and if you reverse time there must be a point where the whole universe was closer together. This is known as the singularity.</li> <li>253. The main evidence for an expanding universe is red shift. This is where light from stars has shifted towards the red end of the spectrum. This happens when the object is moving away.</li> </ul>
		<ul> <li>254. The faster the galaxy is moving away from you the bigger the red shift is.</li> <li>255. Further evidence for the big bang is the existence of cosmic microwave background radiation CMBR. This is high frequency radiation produced in an explosion that has spread out as the universe has grown.</li> <li>256. Although other theories exist the big bang is the only one that explains all the evidence.</li> </ul>
